Abstract

Objective Insulin secretion is regulated by ATP-sensitive potassium (K_{ATP}) channels in pancreatic beta-cells. Peroxisome proliferator-activated receptors (PPAR) α ligands are clinically used to treat dyslipidemia. A PPAR α ligand, fenofibrate, and PPAR γ ligands troglitazone and 15-deoxy- $\Delta^{12,14}$ -prostaglandin J2 are known to close K_{ATP} channels and induce insulin secretion. The recently developed PPAR α ligand, pemafibrate, became a new entry for treating dyslipidemia. Because pemafibrate is reported to improve glucose intolerance in mice treated with a high fat diet and a novel selective PPAR α modulator, it may affect K_{ATP} channels or insulin secretion.

Results The effect of fenofibrate (100 μ M) and pemafibrate (100 μ M) on insulin secretion from MIN6 cells was measured by using batch incubation for 10 and 60 min in low (2 mM) and high (10 mM) glucose conditions. The application of fenofibrate for 10 min significantly increased insulin secretion in low glucose conditions. Pemafibrate failed to increase insulin secretion in all of the conditions experimented in this study. The K_{ATP} channel activity was measured by using whole-cell patch clamp technique. Although fenofibrate (100 μ M) reduced the K_{ATP} channel current, the same concentration of pemafibrate had no effect. Both fenofibrate and pemafibrate had no effect on insulin mRNA expression.

Keywords K_{ATP} channel, PPAR α , fenofibrate, Pemafibrate

Introduction

Diabetes and dyslipidemia are two major global health concerns; they both have strong associations with life threatening ischemic strokes [1].

Clinically, fibrates are used to treat dyslipidemia. In the Action to Control Cardiovascular Risk in Diabetes (ACCORD)-Lipid trial, the major fibrate drug, fenofibrate, improved cardiovascular disease outcomes in high triglyceride (TG) patients [2]. Fibrates are ligands of the nuclear receptor peroxisome proliferator-activated receptor (PPAR) α . PPAR is divided into three subtypes, α , β and γ [3]. PPAR α is known to regulate fatty acid metabolism while γ is known to involve in glucose homeostasis and adipocyte proliferation [4, 5].

Recently, a new PPAR α ligand, pemafibrate, was developed and used in the clinical setting for the treatment of dyslipidemia. Pemafibrate has high selectivity to PPAR α with greater activation capability compared to other fibrate drugs and is classified as a selective PPAR α

modulator (SPPARM α) [6]. Clinically, pemafibrate has also been reported to have a significantly greater effect on decreasing TG levels compared to fenofibrate [7]. In addition to fatty acid regulation, there are reports indicating that PPAR α ligands affect insulin secretion. Sun et al. and Dong et al. reported that PPAR α ligand enhanced glucose-stimulated insulin secretion from isolated rodent islet and beta cell line INS-1 cells [8, 9].

Insulin secretion is stimulated by the closure of ATP-sensitive K⁺ (K_{ATP}) channels in pancreatic beta cells. An increase of intracellular ATP induced by the glucose metabolism closes K_{ATP} channels [10, 11]. The closure of K_{ATP} channels leads to membrane depolarization and opening of voltage dependent Ca²⁺ channels, which allows Ca²⁺ influx, ultimately leading to insulin release [10].

Sulfonylureas and glinides, such as glibenclamide and repaglinide, close K_{ATP} channels and induce insulin secretion; thus, they are used to treat diabetic patients [12, 13].

We previously reported that a PPAR α ligand, fenofibrate, and PPAR γ ligands, troglitazone and 15-deoxy- $\Delta^{12,14}$ -prostaglandin J₂, directly interact with and close K_{ATP} channels and induce insulin secretion in pancreatic beta cell line HIT-T15 cells [14]. Since these PPAR ligands were able to close K_{ATP} channels and induce insulin secretion, it is possible that SPPARM α ligand pemafibrate may also close K_{ATP} channels and induce insulin secretion. Since pemafibrate is widely used clinically, it is important to confirm this possibility.

Here we investigated the effects of pemafibrate, and those of fenofibrate, on K_{ATP} channel activity and insulin secretion.

Materials and methods

Insulin secretion

MIN6 cells, kindly provided by Prof Susumu Seino at Kobe Univ [15], were plated in 6-multiwell plates (1 × 10⁵ cells per well) cultured with high-glucose DMEM medium containing 10% heat-inactivated FBS in a humidified incubator with 95% O₂ and 5% CO₂ at 37 °C. On the day of the experiment, the cells were starved for 1 h in 2 mM glucose solution and replaced with 2 ml of experimental medium and insulin secretion was measured by static incubation (10 min and 60 min). The experimental media were based on the Krebs–Ringer buffer. The Krebs–Ringer buffer contained (in mM) 118.5 NaCl, 2.54 CaCl₂, 1.19 KH₂PO₄, 4.74 KCl, 25 NaHCO₃, 1.19 MgSO₄, and 10 HEPES (pH 7.4 with NaOH) with 0.1% bovine serum albumin. Insulin was measured using ELISA assay kit (Cat No. M1104, Morinaga, Yokohama, Japan). Fenofibrate was purchased from Sigma (Cat No. F6020, St. Louis, MO, USA). Pemafibrate was kindly provided by

Kowa Co. Ltd (Nagoya, Japan). 100 mM stock solutions of pemafibrate and fenofibrate were prepared in DMSO and used in the experiment by diluting 1000× to acquire 100 μM concentration. All control samples contained the same amount of DMSO.

Electrophysiology

Electrophysiological experiments were performed as previously described [16–18]. All electrophysiological measurements were performed at room temperature (22–25 °C) using an EPC-800 patch-clamp amplifier (HEKA, Lambrecht/Pfalz, Germany) and pCLAMP 10 software (Molecular Devices, CA, USA). The pipette solution contained (in mM) 107 KCl, 2 MgCl₂, 1 CaCl₂, 10 EGTA, 10 HEPES, and 0.3 ATP (pH 7.2 with KOH), and the extracellular solution contained (in mM) 138 NaCl, 5.6 KCl, 1 MgCl₂, 10 HEPES, and 2.6 CaCl₂ (pH 7.4 with NaOH). The effects of 100 μM of fenofibrate and pemafibrate on K_{ATP} channel currents were evaluated using the standard whole-cell technique by applying a holding potential of –70 mV with ±10 mV steps at a duration of 250 ms. Data were analyzed using Clampfit software (Molecular Devices).

Reverse transcription-quantitative polymerase chain reaction (qRT-PCR) analysis

The MIN6 cells were exposed to 100 μM fenofibrate or pemafibrate for 2 h. Following the application of drugs, total RNA was isolated using a RNeasy minikit (Cat No. 74104, QIAGEN, Hilden, Germany) and Monarch RNA Purification Columns (Cat No. T2007, New England BioLabs Japan, Inc., Massachusetts, USA). c-DNA synthesis was performed using M-MLV (Cat No. 28025013, Thermo Fisher Scientific, Massachusetts, USA), RNaseOUT Recombinant Ribonuclease Inhibitor (Cat No. 10777019, Thermo Fisher Scientific, Massachusetts, USA), and dNTP (Cat No. 200415, Agilent Technologies, Texas, USA). A quantitative RT-PCR assay was performed using the TB Green Premix Ex Taq II (Tli RNaseH Plus, Cat No. RR820, Takara Bio Inc., Shiga, Japan). The cycling condition was as follows: initial denaturation at 95 °C for 30s, then 40 cycles each at 95 °C for 5s, 56 °C for 10s, and 72 °C for 15s, according to the protocol. Product accumulation was measured in real time and the mean cycle thresholds were determined. The expression levels of Ins1 and Ins2 were calculated using the 2^{ΔΔCT} method of relative quantification and normalized by the housekeeping gene glyceraldehyde-3-phosphate dehydrogenase (GAPDH). The PCR primers are as follows: Ins1 (NM_008386): Fw (CCAGCTATAATCAGAGACCA), Rev (GGGCCTTAGTTGCAGTAGTT), Ins2 (NM_001185083): Fw (AGCGTGGCTTCTTCTACACAC), Rev (CTGGTGCAGCACTGATCTACA),

GAPDH (NM_001289726): Fw (TCCACTCACGGC AAATTCAACG), Rev (TAGACTCCACGACATACT CAGC).

Statistical analysis

All data are expressed as means \pm SEM. The statistical significance of differences was assessed using a paired t-test for electrophysiological changes in currents and one-way ANOVA followed by Tukey's test for insulin secretion and qRT-PCR results. $P < 0.05$ was considered as significant difference.

Results

Effect of pemaifibrate and fenofibrate on insulin secretion from pancreatic beta-cell line

First, we measured the insulin secretion from cultured pancreatic beta-cell line MIN6 cells in various conditions. The 10 min application of fenofibrate in low glucose conditions (2 mM glucose) significantly increased insulin secretion compared to the control and pemaifibrate (Fig. 1a, left). Pemaifibrate application for 10 min did not induce an increase in insulin secretion compared to the control. The amounts of insulin secreted were 6.45 ± 0.14 ng/ml for the control, 8.56 ± 0.45 ng/ml for fenofibrate, and 6.08 ± 0.64 ng/ml for pemaifibrate. In high glucose conditions (10 mM glucose), the 10 min application of fenofibrate tended to increase insulin secretion, but the increase was not statistically significant compared to the control or pemaifibrate (Fig. 1A, right). The amounts of secreted insulin were 12.36 ± 0.86 ng/ml for the control, 14.94 ± 1.14 ng/ml for fenofibrate, and 13.23 ± 0.73 ng/ml for pemaifibrate.

In long term applications, both fenofibrate and pemaifibrate did not show significant differences in insulin secretion compared to the control in low glucose conditions (11.84 ± 0.57 ng/ml for the control, 11.10 ± 0.41 ng/ml for fenofibrate, and 12.26 ± 0.79 ng/ml for pemaifibrate) (Fig. 1b, left). However, in high glucose conditions, fenofibrate showed a significant decrease in insulin secretion (16.77 ± 0.58 ng/ml for the control, 15.07 ± 0.43 ng/ml for fenofibrate, and 16.11 ± 0.32 ng/ml for pemaifibrate) (Fig. 1b, right).

Effect of fenofibrate and pemaifibrate on K_{ATP} channel activity

We recorded the K_{ATP} channel current of MIN6 cells using the whole-cell patch-clamp technique. The application of 20 mM glucose did not affect K_{ATP} channel currents, indicating that the intracellular complex, such as the glycolysis system, is replaced by a pipette solution.

Consistent with the results of our previous study, the application of 100 μ M fenofibrate reduced K_{ATP} channels in MIN6 cells (Fig. 2A). The K_{ATP} channel current

before the application of fenofibrate (the control) was 28.46 ± 5.11 pA/pF, while after the application of fenofibrate it was 10.27 ± 1.78 pA/pF. The application of 100 μ M pemaifibrate showed no effect on the K_{ATP} channel current (Fig. 2b). The K_{ATP} channel current before the application of pemaifibrate (the control) was 36.66 ± 10.46 pA/pF, while after the application of pemaifibrate it was 30.94 ± 7.11 pA/pF. The current recorded in this study was confirmed to be the K_{ATP} channel current by applying a selective blocker of the K_{ATP} channel (100 μ M tolbutamide).

Effect of fenofibrate and pemaifibrate on insulin mRNA expression in MIN6 cells

Because fenofibrate showed a significant reduction of insulin secretion in long term application under high glucose conditions, we measured the influence of these two drugs on insulin gene expression. No difference in Ins1 or Ins2 mRNA expression was confirmed after 100 μ M of fenofibrate or pemaifibrate applications (Fig. 3a, b).

Discussion

In the present study, we showed that SPPAR α pemaifibrate has no direct effect on insulin secretion, whereas the PPAR α ligand fenofibrate blocks K_{ATP} channels, increases short term insulin secretion in low glucose conditions, and reduces long term insulin secretion in high glucose conditions.

PPAR α ligands are reported to have glucose-lowering effects in type 2 diabetic patients and diabetic model mice [8, 19, 20]. The underlying mechanism for lowering glucose is considered to be the ligands acting on both insulin sensitivity and pancreatic beta-cells. Regarding the effect on insulin sensitivity, PPAR α ligands are reported to increase TG and fatty acid metabolism, thus reducing the fatty acid contents in tissues such as those in the liver and skeletal muscle [21, 22]. In addition, suppression of inflammatory cytokine production from monocytes is also considered to be a mechanism of improving insulin sensitivity [23]. Regarding the effects of PPAR α ligands on pancreatic beta-cells, fenofibrate is reported to potentiate glucose-stimulated insulin secretion (GSIS) under high palmitate conditions [8]. Pemaifibrate is also reported to improve insulin secretion by increasing the expression of ATP-binding cassette protein A1 (ABCA1), which is a critical regulator of cholesterol and phospholipid efflux [9]. It is likely that PPAR α ligands indirectly improve pancreatic beta-cell function by ameliorating lipotoxicity. However, reports are showing PPAR α ligands stimulating insulin secretion by directly acting on beta-cell function. Pemaifibrate is reported to ameliorate oxidative stress of pancreatic beta-cells [24]. Since the expression of antioxidant enzymes are low in pancreatic beta-cells [25], the

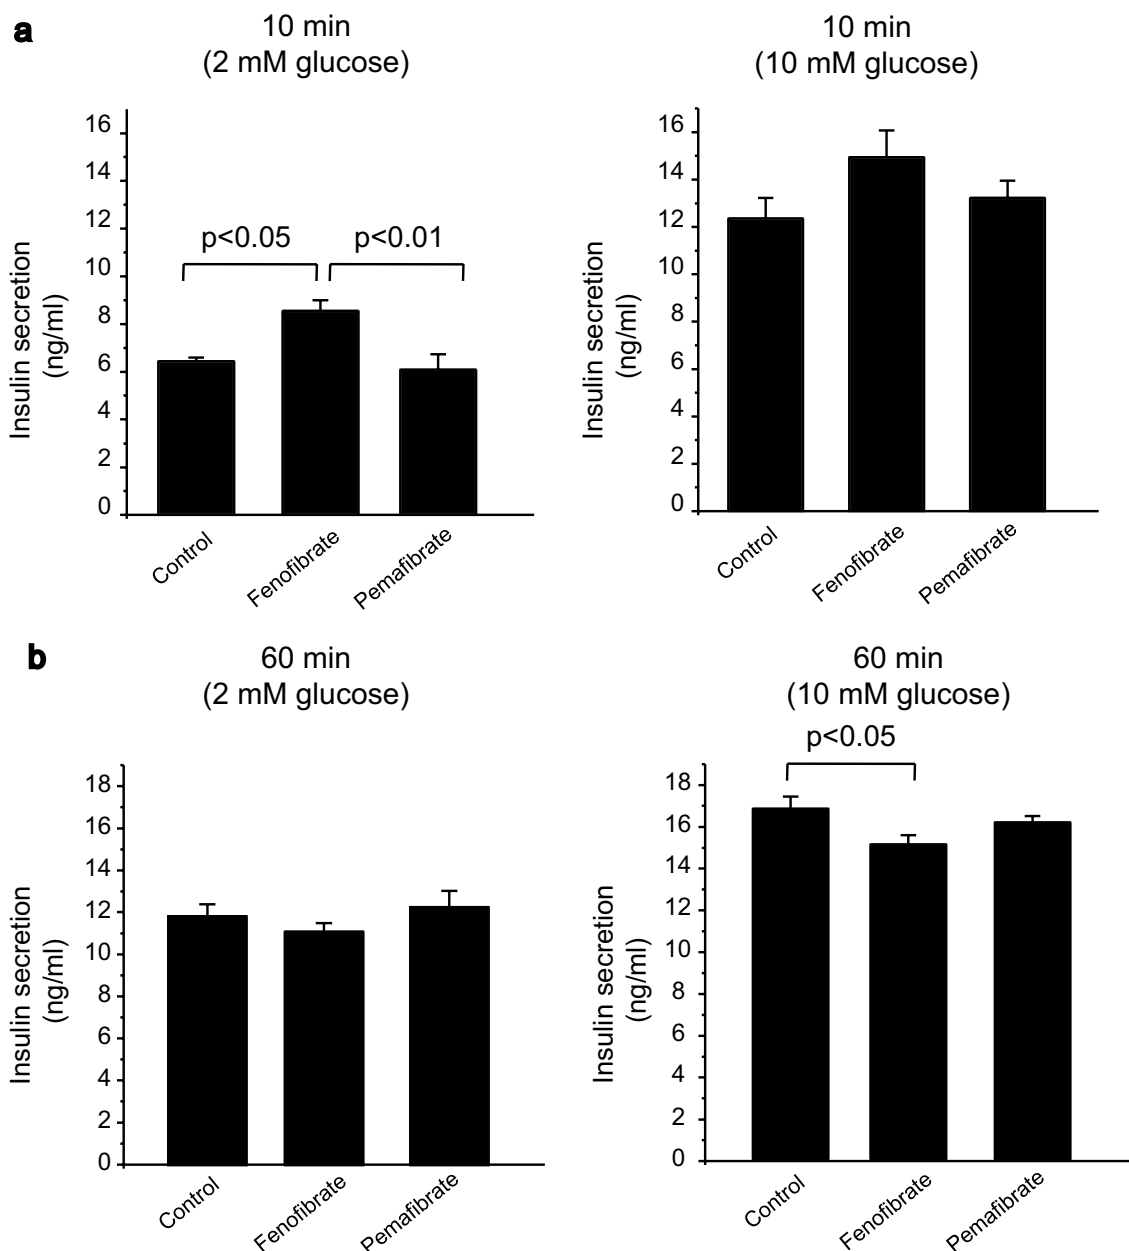

Fig. 1 The effect on insulin secretion of fenofibrate and pemaifibrate on MIN6 cells. **a** Insulin secretion from MIN6 cells for 10 min incubation of control, pemaifibrate (100 μM), and fenofibrate (100 μM) in 2 mM glucose (left) and 10 mM glucose (right) conditions (n=6 independent wells in each condition). **b** Insulin secretion from MIN6 cells for 60 min incubation of control, pemaifibrate (100 μM), and fenofibrate (100 μM) in 2 mM glucose (left) and 10 mM glucose (right) conditions (n=6 independent wells in each condition)

effect of pemaifibrate on reducing oxidative stress is more in the maintaining of beta-cell condition rather than the insulin secretion process. However, we have shown in the past that fenofibrate directly affects the insulin secretion process by closing K_{ATP} channels.

The K_{ATP} channels are a key factor in regulating insulin secretion in pancreatic beta-cells. The ATP produced from glucose metabolism directly interacts with, and

closes, K_{ATP} channels, and induces insulin secretion. Reduction of ATP sensitivity in K_{ATP} channels induces a reduction in insulin secretion. The reduction of ATP sensitivity of K_{ATP} channels due to mutation can cause a special type of diabetes known as neonatal diabetes [26, 27].

In the present study, fenofibrate significantly increased insulin secretion in short term applications in low glucose conditions, and only tended to increase

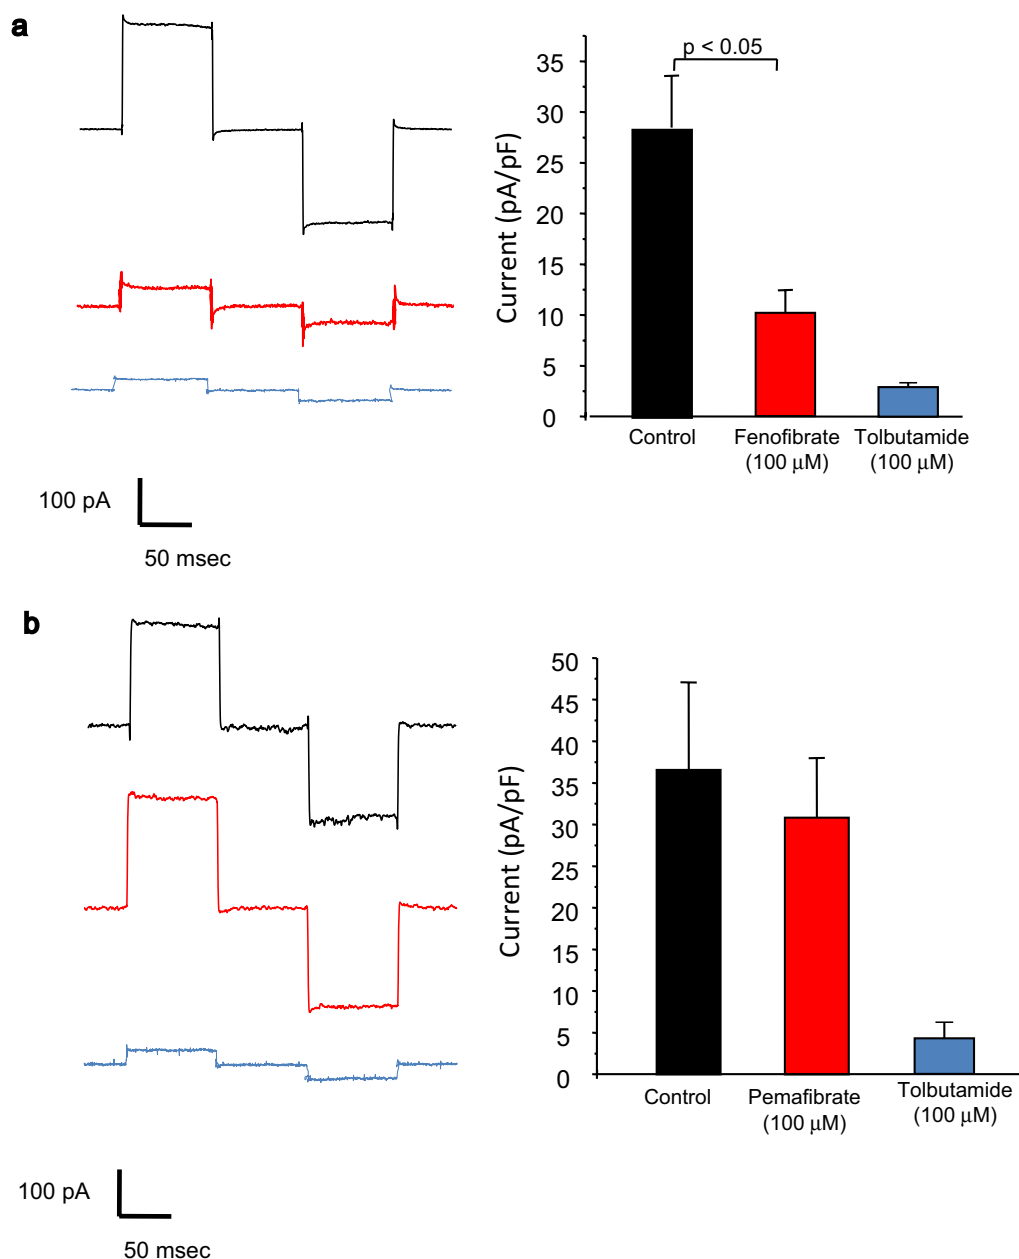

Fig. 2 Effect of fenofibrate and pemafibrate on K_{ATP} channel activity. **a** left: Representative K_{ATP} channel recordings from MIN6 cells before (black), after application of 100 μM fenofibrate (red) and after application of 100 μM tolbutamide (blue) during the holding potential of -70 mV with ±10 mV steps at a duration of 250 ms; right: Bar graph showing the summary of K_{ATP} channel currents of MIN6 cells before (black), after application of fenofibrate (red) and after application of tolbutamide (blue). n = 10 cells. **b**, left: Representative K_{ATP} channel recordings from MIN6 cells before (black), after application of 100 μM pemafibrate (red) and after application of 100 μM tolbutamide (blue) during the holding potential of -70 mV with ±10 mV steps at a duration of 250 ms; right: Bar graph showing the summary of K_{ATP} channel currents of MIN6 cells before (black), after application of pemafibrate (red) and after application of tolbutamide (blue). n = 10 cells

under high glucose conditions. This may be explained in that the increase of intracellular ATP reflecting high glucose conditions may overcome the inhibitory effect of fenofibrate on K_{ATP} channels. Further study of fenofibrate on K_{ATP} channel kinetics is required to elucidate

the details of the mechanism for fenofibrate blocking the channels.

To date, there are no reports of hypoglycemia from patients under fenofibrate treatment. This is because fenofibrate is rapidly converted into fenofibric acid, the

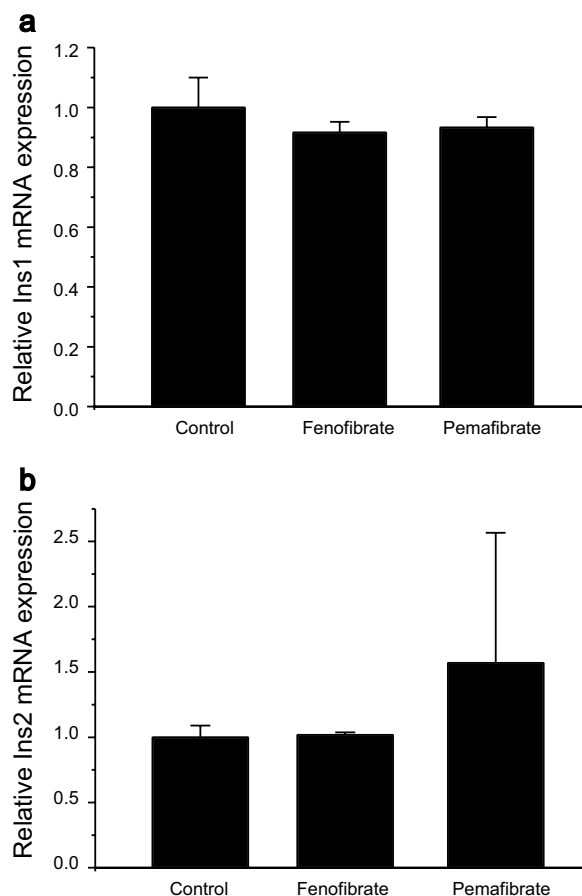

Fig. 3 Relative expression of insulin mRNA expression with fenofibrate and pemaifibrate application. **a** Relative mRNA expression of Ins1 mRNA control, and after 2 h fenofibrate (100 μ M) and pemaifibrate (100 μ M) application on MIN6 cells. $n=5$ each from independent experiment. **b** relative mRNA expression of Ins2 mRNA control, and after 2 h fenofibrate (100 μ M) and pemaifibrate (100 μ M) application on MIN6 cells. $n=5$ each from independent experiment

pharmacologically relevant form of PPAR α , in liver and plasma [28]. However, we have shown in our previous study that fenofibric acid also closes K_{ATP} channels and induces insulin secretion in high doses. In addition, PPAR γ agonists, such as troglitazone and 14-deoxy $\Delta^{12,14}$ -PGJ $_2$, have been confirmed to close K_{ATP} channels and induce insulin secretion [14]. Therefore, with pemaifibrate being a highly specific ligand of PPAR α and fibrate class drug, it is important to confirm whether it affects K_{ATP} channels and insulin secretion similar to fenofibrate or PPAR γ ligands. The present study clearly shows that pemaifibrate does not affect K_{ATP} channel activity, insulin secretion, or insulin gene expression. Structurally, fenofibrate and pemaifibrate have a common acidic region but pemaifibrate uniquely contains benzoxadole and phenoxyalkyl side chains (Fig. 4).

Fig. 4 Structure of fenofibrate and pemaifibrate

These structural differences may contribute to different effects on insulin secretion and K_{ATP} channel activity.

Although pemaifibrate showed no effect on insulin secretion, we have shown in this study that 60 min applications of fenofibrate can significantly reduce insulin secretion compared to the control in high glucose conditions. In the past, Ramarkrishnan et al. reported that mice treated with fenofibrate for 4 weeks showed a reduction in insulin secretion [29]. The underlying mechanism for this in vivo effect of a reduction of insulin secretion induced by fenofibrate treatment was clarified to be a mechanism compensating for the increased plasma insulin level due to the fenofibrate's PPAR α activation-triggered reduction of insulin clearance in the liver. In the same report, it was further confirmed that in vitro experiments using islets isolated from the same mice did not show an increase in insulin secretion. This is in direct contrast to the findings of the present study. Because insulin mRNA expression was not affected by the fenofibrate in our study, the underlying mechanism for our results may not involve the transcriptional activity of insulin genes. The fact that this effect was only observed in high glucose conditions may indicate the involvement of glucose metabolism. Further studies are required.

Conclusions

While fenofibrate can inhibit the K_{ATP} channel and induce a significant increase of insulin secretion in low glucose concentration within 10 min, pemaifibrate showed no such effect. It indicates that when these drugs are clinically used to treat dyslipidemia, fenofibrate may increase insulin secretion while pemaifibrate has no such effect. In addition to the pharmacological actions we

have shown in this study, our current findings contain important information on possible additional effects and pharmacological mechanism of PPAR α ligands. Clinically, the findings of the present study that suggest the possible involvement of PPAR α ligands in insulin secretion provide new information for the treatment of diabetes as well.
